

Unified Web Application Security And Delivery

Web application security and delivery frequently go hand in hand, which is why many organizations combine their web application firewall (WAF) and content delivery network (CDN) with a single solution. Radware’s integrated CDN provides unified, secure web application delivery within a single solution by combining Radware’s industry-leading Cloud WAF Service together with the high-performance capabilities of AWS CloudFront, enabling fast and secure delivery of web applications and content.

Unified solution

Radware’s CDN solution is directly and seamlessly integrated into its Cloud WAF Service, with a unified management portal. This enables managing the security and delivery of each application directly from within a single source, with an intuitive, easy-to-use dashboard. Radware’s unified solution enables end-to-end management of website security and delivery, with a full-featured CDN, backed by comprehensive security with Radware’s Cloud WAF Service, Bot Manager, API security, and L7 DDoS protection.

Industry-Leading Security

Whereas other unified CDN/WAF offerings rely only on a negative security model based on static, manually-configured security policies, Radware’s solution is backed by its industry-leading WAF technology, based on a positive security model. This provides full protection not only against traditional OWASP Top 10 threats, but also against zero-day attacks for which there are no existing rules, or web attacks which have otherwise not been enabled in security policies.

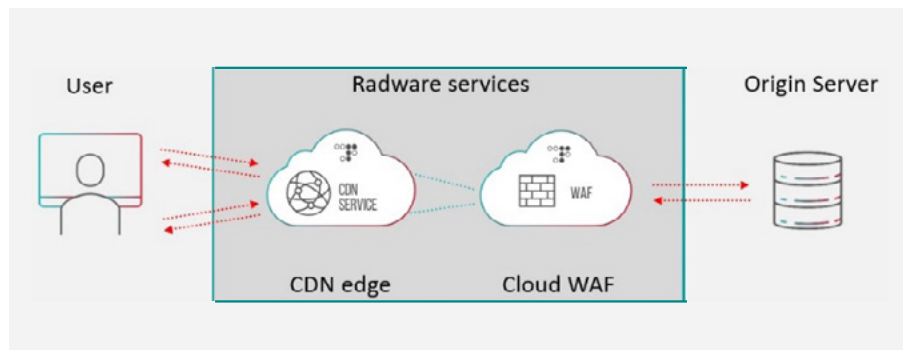

Cloud Native Integration

With as much as 70% of production applications already deployed in cloud environments, Radware’s integrated CDN, based on AWS CloudFront CDN, offers a cloud-native, DevOps friendly solution. This allows organizations and DevOps professionals to benefit from Radware’s superior security while maintaining their existing application delivery processes.

Unified Architecture

Radware’s integrated CDN solution offers a unified architecture, completely transparent both to end users and application managers. Cached content will be served directly from the nearest location, closest to the customer, whereas Radware’s WAF will directly protect the origin against malicious requests.
